Abstract

An endo-perio lesion can have varied pathogenesis which can range from simple to complex. The success of a combined periodontal and endodontic lesion depends on the elimination of both of these disease processes. In case of a combined endo-perio lesion, the endodontic therapy results in healing of the endodontic component of involvement while the prognosis of tooth would finally depend on the healing of the periodontal structures. This article includes case report of combined endo-perio lesion which was first treated with conventional endodontic therapy and then followed by periodontal surgery.
